Abstract

Understanding Bash code is challenging for developers due to its syntax flexibility and unique features. Bash lacks sufficient training data compared to comment generation tasks in popular programming languages. Furthermore, collecting more real Bash code and corresponding comments is time-consuming and labor-intensive. In this study, we propose a two-module method named Bash2Com for Bash code comments generation. The first module, NP-GD, is a gradient-based automatic data augmentation component that enhances normalization stability when generating adversarial examples. The second module, MASA, leverages CodeBERT to learn the rich semantics of Bash code. Specifically, MASA considers the representations learned at each layer of CodeBERT as a set of semantic information that captures recursive relationships within the code. To generate comments for different Bash snippets, MASA employs LSTM and attention mechanisms to dynamically concentrate on relevant representational information. Then, we utilize the Transformer decoder and beam search algorithm to generate code comments. To evaluate the effectiveness of Bash2Com, we consider a corpus of 10,592 Bash code

2 Bash Comment Generation via Data Augmentation and Semantic-Aware CodeBERT

and corresponding comments. Compared with the state-of-the-art baselines, our experimental results show that Bash2Com can outperform all baselines by at least 10.19%, 11.81%, 2.61%, and 6.13% in terms of the performance measures BLEU-3/4, METEOR, and ROUGR-L. Moreover, the rationality of NP-GD and MASA in Bash2Com are verified by ablation studies. Finally, we conduct a human evaluation to illustrate the effectiveness of Bash2Com from practitioners' perspectives.

Keywords: Bash code, Code comment generation, Adversarial training, Data augmentation

1 Introduction

Bash, the default programming language of Linux shell, is a crucial tool for developing and maintaining the Linux operating system [1]. However, its syntax flexibility and lack of explicit structure can pose challenges for developers seeking to understand Bash scripts in the context of developing and maintaining software systems [2]. According to our statistics, more than 151,640 posts on Stack Overflow are searching for the keyword “Bash” until February 22, 2023. For instance, Fig. 1 shows a post¹ which indicates that the user cannot understand a Bash snippet. The expression `-z` string is true if the length of the string is zero. This is difficult for people who are just engaged in software development and are not experienced developers in this field. Automatically generating comments for Bash code is necessary due to the difficulty in understanding the semantics of Bash code, especially for developers unfamiliar with Bash code.

Program understanding is crucial for software development, maintenance, and reuse. In practice, developers usually spend an average of 59% of their time on understanding programs [3]. Naturally, high-quality comments can improve program understanding efficiency significantly [4]. Existing automatic code comment generation work focuses on popular programming languages (such as Java and Python, and so on) [5–8]. However, few works of comment generation focus on domain-specific languages (such as Bash [9]), which should be solved urgently.

Compared to other programming languages, generating code comments for Bash is challenging due to insufficient training data. The current corpus available for studying Bash comment generation is limited to 10,592 data pairs, as reported in a recent study by Yu et al. [9]. To overcome this limitation, more realistic Bash code and corresponding comments must be collected, which can be time-consuming and labor-intensive. To address this issue, we propose Normalized Projected Gradient Descent(NP-GD), a gradient-based adversarial training that uses generated adversarial examples to augment the training data and improve model performance. Previous studies have not investigated

**This question already has answers here:**[Is there a list of 'if' switches anywhere?](#) (5 answers)

Closed 6 years ago.

I'm looking at the following code:

```
if [ -z $2 ]; then
    echo "usage: ..."
```

(The 3 dots are irrelevant usage details.)

Maybe I'm googling it wrong, but I couldn't find an explanation for the `-z` option.**bash****Fig. 1** A Stack Overflow post on understanding of a Bash snippet

whether adversarial training in the Bash comment generation task can enhance model performance [2, 9, 10].

Moreover, previous studies have failed to fully leverage Bash code's semantic representation information. Specifically, BASHEXPLAINER [9] used the vector output of the last layer of the 12-layer CodeBERT [11] as the coding vector of this sentence. However, Kondratyuk et al. [12] found that relying solely on the output vector of the final layer may result in the loss of valuable information that other layers, such as the lower and middle layers of BERT can capture. According to Jawahar et al., [13], the level of semantic information decreases as the encoder layer becomes shallower in CodeBERT. In contrast, the level of semantic information increases as the encoder layer becomes deeper. Su et al. [14] further investigated this phenomenon and found that each layer of BERT offers a rich source of linguistic information through its output representation. Lower layers capture surface features, middle layers capture syntactic features, and higher layers capture semantic features. To address the issue of insufficient utilization of semantic information in Bash code, we propose a solution called Memory Attention Semantic-Aware (MASA). This method fully captures the learned information and enhances CodeBERT's semantic awareness.

In this study, we propose a novel method Bash2Com for generating Bash code comments. Specifically, Bash2Com includes two mentioned components: the data augmentation component NP-GD and the semantic-aware component MASA. In particular, the adversarial examples generated by NP-GD are added to the training data, which allows the model to learn more knowledge from the adversarial examples to improve generalization. MASA learns a rich semantic

4 Bash Comment Generation via Data Augmentation and Semantic-Aware CodeBERT

representation fed into the Transformer decoder. Afterward, MASA utilizes the beam search algorithm [15] to generate comments for Bash code.

To evaluate the effectiveness of Bash2Com, we conducted experiments on the corpus shared by Yu et al. [9]. Our evaluation includes a recent Bash comment generation baseline proposed by Yu et al. [9], as well as state-of-the-art baselines from the source code summarization research domain including information retrieval methods [5, 16–18], deep learning methods [11, 19–24] and hybrid methods [9, 18, 25]. Both evaluation and case study results demonstrate that Bash2Com outperforms all baseline methods. In the next step, we conduct ablation research to verify the rationality of the component settings in our proposed method. Specifically, we consider four methods (i.e., FGSM [26], FGM [27], PGD [28], and NP-GD) in the data augmentation component and consider three different RNNs (i.e., GRU [29], Bi-LSTM [30], and LSTM [31]) in the semantic-aware component. The results of our ablation experiments indicate that the best performance is achieved by selecting NP-GD and LSTM. Finally, we conducted a human evaluation to demonstrate that Bash2Com outperforms baseline methods from practitioners’ perspectives regarding informativeness, naturalness, and similarity.

In summary, the main contributions of our work can be summarized as follows:

- We propose a novel Bash comment generation method Bash2Com, which includes two components NP-GD and MASA. Specifically, NP-GD enhances the data representation, and MASA improves the semantic information representation learned by each layer in CodeBERT.
- We conduct experiments on a high-quality corpus shared by Yu et al. [9], and the empirical results show our method’s effectiveness and the rationality of the component settings.
- We share empirical corpus and scripts on our project homepage ² to promote the replication of our research and encourage more follow-up research on this research topic.

The rest of this paper is organized as follows: Section 2 offers some background on data augmentation technology and CodeBERT. Section 3 describes the framework and details of our proposed method. Section 4 shows our empirical settings. Section 5 presents our result analysis for research questions. Section 6 analyzes potential threats to our empirical results. Section 7 summarizes related studies to our work and emphasizes the novelty of our study. Finally, Section 8 summarizes our work and shows potential future directions.

2 Research Background

2.1 Data Augmentation in NLP

In natural language processing (NLP), typical data augmentation methods can be categorized as rule-based [32, 33] and gradient-based [26, 27]. The method of data augmentation based on rules is easy to use, but it has certain limitations. For instance, it requires manual rule setting, which results in less coverage and poor diversity. While these methods are effective for natural languages, there are significant syntactic differences between Bash code and natural language. Therefore, a simple rule-based approach may not apply to Bash code. The method of data augmentation based on gradients is known as adversarial training. This involves training a model with initial examples and generating adversarial examples that can resist attacks and improve the model's robustness. Gradient-based data augmentation methods have been successfully applied to many tasks (such as object detection [34], segmentation [35], image classification [36], Text classification [37]). The fundamental concept of adversarial training can be expressed through the following Max-Min formula [28].

$$\min_{\theta} \mathbb{E}_{(x,y)} \sim D \left[\max_{\|\delta\| \leq \epsilon} L(f_{\theta}(x + \delta), y) \right] \quad (1)$$

where x represents the input to the model. δ represents the perturbation superimposed on the input. $f_{\theta}()$ is the neural network function. y is the label of the example. $\max(L)$ is the optimization objective to find the perturbation that maximizes the loss function. D is the training set. E is the maximum likelihood estimation.

2.2 CodeBERT

CodeBERT is a pre-trained model based on the transformer architecture [38], which operates in dual mode using both natural language (NL) and programming language (PL) encoders. It has been pre-trained on a large-scale corpus [39] with two self-supervised tasks: Masked Language Model (MLM) [40] and Replaced Token Detection (RTD) [41]. The MLM task utilizes bi-modal data, feeding the code with corresponding comments and randomly masking positions to replace the token with a special token [MASK]. The objective of the MLM task is to predict the original token, with the loss function defined as follows.

$$L_{MLM}(\theta) = \sum_{i \in m^w \cup m^c} -\log p^{D_1}(x_i | \mathbf{w}^{\text{masked}}, \mathbf{c}^{\text{masked}}) \quad (2)$$

where p^{D_1} is the predicted token by model. m^w and m^c are the random set of positions for NL and PL to mask as the token [MASK], which means w^{masked} and c^{masked} . x is the input, expressed as $x = w + c$.

6 *Bash Comment Generation via Data Augmentation and Semantic-Aware CodeBERT*

The RTD task utilizes uni-modal code and comment to train the data generator to restore the randomly masked token. The loss function of the RTD task is defined as follows.

$$L_{RTD}(\theta) = \sum_{i=1}^{|w|+|c|} \left[\delta(i) \log p^{D_2}(\mathbf{x}^{\text{corrupt}}, i) + (1 - \delta(i))(1 - \log p^{D_2}(\mathbf{x}^{\text{corrupt}}, i)) \right] \quad (3)$$

$$\delta(i) = \begin{cases} 0, & \text{if } x_i^{\text{corrupt}} = x_i \\ 1, & \text{otherwise.} \end{cases} \quad (4)$$

where θ is the discriminator parameter, $\delta(i)$ is an indicator function, and p^{D_2} is the discriminator that predicts the probability of the i -th word being original. The RTD randomly replaces the token to know whether the token is original words through the discriminator, a binary classification problem.

3 Our Approach

Our proposed method, called Bash2Com, consists of two main parts: *Data Augmentation* and *Model Architecture*, as illustrated in Fig. 2. The data augmentation part is designed to enhance the representation of Bash code for a small corpus, while the model architecture part aims to better represent semantic information by combining the knowledge learned from each layer in CodeBERT.

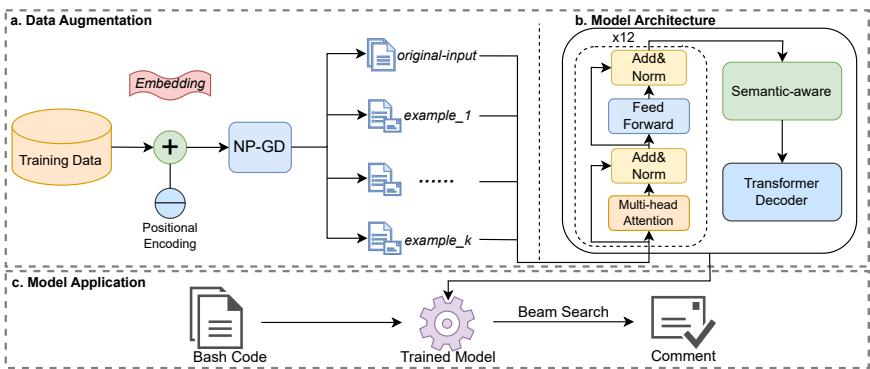

Fig. 2 Overall framework of our method Bash2Com.

3.1 Data Augmentation

We propose a novel gradient-based method, NP-GD, to generate reliable training samples for data augmentation automatically. NP-GD combines the

Bash Comment Generation via Data Augmentation and Semantic-Aware CodeBERT

benefits of L_1 and L_2 normalizations [42] and improves the Projected Gradient Descent (PGD) method [28], enhancing the stability of the normalization process.

Word Embedding. In the standard encoder-decoder architecture, the word embedding layer captures the relationships between tokens by mapping the text to a vector representation. For the given Bash code X , the input to the model is tokenized by the BPE algorithm [43] to obtain the sequence $x = (x_1, \dots, x_N)$, where N is the length of this sequence. To unify the length of the input sequence, we utilize padding or truncation operations. Thus, the output of the word embedding layer can be guaranteed to be uniform $\mathbf{x} = (\mathbf{x}_1, \dots, \mathbf{x}_n)$. At the same time, we add absolute position encoding (APE) [38] in the embedding layer to better extract the code representation information. Thus the final output is $\mathbf{x} = \mathbf{x} + APE(\mathbf{x})$, $\mathbf{x} \in \mathbb{R}^{batch \times n \times d_{model}}$.

Most adversarial training methods in natural language [26–28, 37, 44] add perturbations to the embedding layer. Compared to adding perturbations directly to the original samples, the subtle perturbations added to the embedding layer have minimal impact on semantics, effectively increasing the number of correct examples in the training data [45, 46], thereby enhancing model performance. Therefore, we adopt the same approach as previous natural language processing methods and generate examples by perturbing the embedding layer.

NP-GD. For a given input embedding sequence \mathbf{x} , NP-GD aims to add perturbation δ and generate K adversarial examples $\{\mathbf{x}_{adv}^i\}_{i=1}^K$. Each \mathbf{x}_{adv} is semantically similar to \mathbf{x} but different from the source input. The original input \mathbf{x} together with the adversarial examples $\{\mathbf{x}_{adv}^i\}_{i=1}^K$ is utilized as the training data to fine-tune CodeBERT.

Our method, NP-GD, is inspired by the concept of PGD [28] and employs a multi-iteration attack to compute gradients and perturbations. Like PGD, NP-GD solves the internal maximization problem iteratively, with each iteration projecting the perturbation to a specified range. Specifically, in each iteration of the attack, NP-GD first calculates the gradient g_t of the input \mathbf{x}_t at that time, where,

$$g_t = \frac{\partial L(f_\theta(\mathbf{x}_t, y))}{\partial \theta}. \quad (5)$$

Then NP-GD computes the perturbation δ_{t+1} as follows,

$$\delta_{t+1} = \alpha(g_t \cdot \|g_t\| / |g_t|) \quad (6)$$

where α denotes the step size. The normalization method used in PGD is L_∞ normalization. However, the solutions obtained by L_∞ normalization are usually not sparse and do not guarantee to reduce the complexity of the model. To alleviate this issue, our proposed NP-GD takes the L_1 normalization method into account inspired by the study of Simon-Gabriel et al. [47], as shown in Equation 6. Specifically, it performs L_1 normalization on the vectors and then applies L_2 normalization to the generated vectors. NP-GD has the advantage of using L_1 normalization to reduce the effect of large values on the vectors

and then applying L_2 normalization to ensure that the resulting vectors have a consistent length and sum to 1. Therefore, NP-GD can improve the stability of the normalization process while retaining the advantages of L_1 and L_2 normalization.

Finally, NP-GD can obtain the batch data \mathbf{x}_{t+1} by adding a perturbation δ_{t+1} as follows.

$$\mathbf{x}_{t+1} = \Pi_{\mathcal{S}} (\mathbf{x}_t + \delta_{t+1}) \quad (7)$$

where \mathcal{S} denotes the constraint space of the perturbation δ and its value is limited between 0 and 1. In our study, we keep the value of \mathcal{S} as 0.01. Specifically, \mathcal{S} ensures that the adversarial examples we generated are semantically unchanged from the original input. This can ensure the semantic invariance of examples as much as possible. Moreover, because noise is also a data augmentation method [48], Bash2Com can accept examples with semantic changes and consider them reasonable errors. NP-GD continues to compute the gradient g_{t+1} on the new batch data input \mathbf{x}_{t+1} and repeat the previous steps. After the above steps are iterated K times, NP-GD gets the accumulated gradients by K attacks and then executes gradient descent to update Bash2Com parameters.

3.2 Model Architecture

To extract more semantic information from the various layers of representational data output by CodeBERT, we introduce a new semantic-aware method called MASA, which aids in producing high-quality Bash comments. MASA dynamically focuses on pertinent representational information using LSTM and attention mechanisms. We then utilize the Transformer decoder to generate Bash code comments from the vector representations fused by MASA. The detailed architecture of this part is illustrated in Fig. 3.

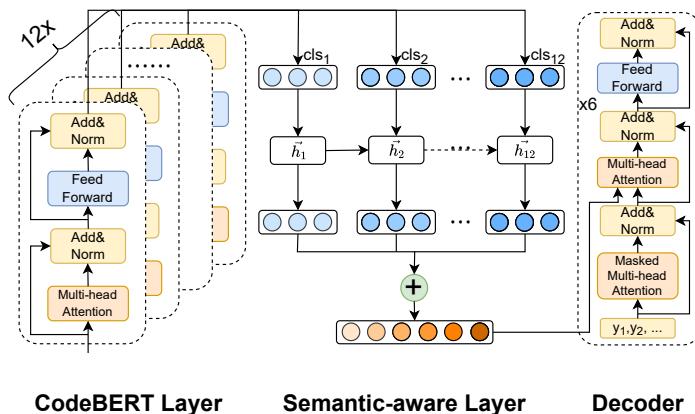

Fig. 3 The model architecture of MASA

Bash Comment Generation via Data Augmentation and Semantic-Aware CodeBERT

CodeBERT Layer. In this layer, we construct an encoder model by using CodeBERT, which generates better semantic representation information for Bash code by fine-tuning CodeBERT. Specifically, for a given input embedding sequence \mathbf{x} , CodeBERT feeds it into the model to obtain a set of semantic vectors $\{\mathbf{x}_{enc}^i\}_{i=1}^{12}$ from all layers, where each $\mathbf{X}_{enc} \in \mathbb{R}^{batch \times n \times d_{model}}$.

Semantic-aware Layer. In this layer, we aim to extract sufficient semantic representations of the target input and combine each layer's semantics according to its weights. Generally speaking, researchers extract the vector of the first token from the encoder in the last layer of CodeBERT as an aggregate sequence representation in previous studies [9, 12, 13, 49]. To compute the attention score, we extract the vector of the first token of each layer in CodeBERT as the semantic representation and connect them to a new semantic representation vector \mathbf{X}_{Sem} to better use the rich representation information learned by the layers in the pre-trained model. CodeBERT utilizes a 12-layer encoder for pre-training, which is expressed as $\mathbf{X}_{Sem} \in \mathbb{R}^{batch \times 12 \times d_{model}}$. Jawahar et al. [13] found that the shallower the encoder layer of the BERT model, the lower the semantic information represented, while the deeper the encoder layer of the BERT model, the higher the information represented. Therefore, \mathbf{X}_{Sem} can represent the semantic relationship from shallow to deep in CodeBERT.

Given the aforementioned characteristics, attempting to learn all semantic information through LSTM is natural. As shown in Fig. 2, we utilize an LSTM, which contains 12 cells for learning for a given input $\mathbf{X}_{Sem} = (\mathbf{X}_1, \dots, \mathbf{X}_i, \dots, \mathbf{X}_{12})$. Each semantic information in \mathbf{X}_{Sem} is represented by the implicit vector learned by LSTM as follows.

$$\vec{h}_i = \overrightarrow{\text{LSTM}}(\mathbf{X}_i), \quad i \in [1, 12] \quad (8)$$

Not all representative information contributes equally to a given target input. Certain source code-related tasks may emphasize low-level representation information [12], while others may prioritize high-level representation information [50]. To extract more significant representation information, we employ an attention mechanism. Specifically, we first convert \mathbf{h}_i to \mathbf{u}_i via the full connection layer $\mathbf{u}_i = \tanh(W\mathbf{h}_i + b)$. Then, the similarity with the context vector can be calculated and converted into probability distribution by Softmax as follows.

$$\alpha_i = \frac{\exp(u_i^T u_w)}{\sum_i \exp(u_i^T u_w)} \quad (9)$$

where α_i can be treated as the importance of the output vector for each layer. Therefore, using α_i as a global weighted summation over $\{\mathbf{h}_i\}_{i=1}^{12}$ can generate the input vector \mathbf{X}_{out} for decoder layer as the fusion of Fig. 3 shows.

$$X_{out} = \sum_i^{12} \alpha_i h_i \quad (10)$$

Decoder Layer. We utilize the Transformer decoder as the decoder module in our framework. Transformer [38] leverages an auto-regressive mechanism to predict the next possible word in the generation process based on previous content. Therefore, inferring the subsequent output from the encoder part’s output is necessary. Each decoder layer utilizes an attention mechanism for the \mathbf{X}_{out} output by MASA. Other operations are consistent with those of the CodeBERT encoder. Finally, the decoder output is passed to a fully connected neural network. The network predicts the probability of the next token through the Softmax layer, which can be defined as follows.

$$P(y_{t+1} | y_1, \dots, y_t) = \text{softmax}(W \cdot X_{\text{out}} + b) \quad (11)$$

where y denotes the predicted token. We train our model parameters θ by the loss function L for a given input text x based on cross-entropy, defined as follows.

$$L = - \sum_{i=1}^{|y|} \log P_\theta(y_i | y < i, x) \quad (12)$$

3.3 Model Application

Our trained model can generate relevant comments by analyzing the application developer’s Bash code. As the output of Bash2Com is a comment, which can be treated as a token sequence, we employ beam search [51] to enhance performance.

Beam search returns a list of the most probable output sequences, providing developers with a selection of the most likely comments. This method involves iteratively examining the comment tokens of every step to select the lowest cost k tokens, where k represents the beam width. After pruning any residual branches, the process identifies potential tokens for subsequent steps until reaching the end-of-sequence marker. Ultimately, our model generates and returns k candidate comments for each Bash code. These candidates are then ranked based on their average probabilities throughout the beam search process.

4 Experimental Setup

Our empirical study aims to answer the following three research questions.

- RQ1: How successful is our proposed method, Bash2Com, in generating Bash comments?
- RQ2: How much does our proposed component, NP-GD, contribute to the effectiveness of our proposed method, Bash2Com, in achieving its objectives?
- RQ3: How much does our proposed component, MASA, contribute to the effectiveness of our proposed method, Bash2Com, in achieving its objectives?

4.1 Experimental Subject

Our study considers the corpus shared by Yu et al. [9] as our experimental subject. They expanded the corpus shared by NL2Bash [2] with the corpus shared by the NLC2CMD competition. Then, they removed the duplicate samples from the expanded corpus, and a high-quality corpus containing 10,592 samples was finally constructed. The statistical information for this corpus is presented in Table 1. The data reveals that most of the Bash code and its corresponding comments in the corpus consist of approximately 8 or 11 words. Furthermore, it was found that 99.9% Bash code and its corresponding comments in the corpus are no longer than 48 words.

Table 1 Statistics for length of samples in the corpus

Code length statistics					
Average	Mode	Median	<16	<32	<48
8.528	4	7	90.8%	99.7%	99.9%
Code comment length statistics					
Average	Mode	Median	<16	<32	<48
11.874	10	11	80.3%	99.5%	99.9%

In our empirical study, we used a random sampling method to divide the corpus into three sets: a training set, a validation set, and a test set. The split ratio was 80% for training, 10% for validation, and 10% for testing. This ratio is consistent with the settings used in a previous study [9] to ensure a fair comparison.

4.2 Performance Measures

To quantitatively compare the performance between our proposed method and baselines, we consider three performance measures (i.e., BLEU [52], METEOR [53], and ROUGE-L [54]). These performance measures have been extensively utilized in previous studies on neural machine translation and automatic code comment generation [18, 55–62]. The higher the performance measure of these metrics, the better the performance of the corresponding method.

To ensure consistency in the performance measures and avoid any discrepancies due to differences in their implementation, we utilize the implementation provided by the nlg-eval library³ for three performance measures, which can mitigate threats to internal validity.

4.3 Baselines

To demonstrate the competitiveness of Bash2Com, we compared it with state-of-the-art baselines. Specifically, BASHEXPLANER [9] is the only baseline of the Bash code comment generation task, and others are the baselines of related

³<https://github.com/Maluuba/nlg-eval>

work for similar tasks (such as source code summarization). In summary, our selected baselines can cover three types of methods.

The first category includes four information retrieval-based methods.

- **LSI** [16] retrieves similar code by computing the distance between the text and words in the corpus.
- **VSM** [17] utilizes the feature vector of the code for retrieval and uses the cosine similarity from the training set.
- **BM25** [18] is a bag-of-words retrieval function to estimate the relevance between documents and a given search query.
- **NNGen** [5] generates commit messages based on nearest neighbors, which ranks code based on cosine similarity and BLEU value.

The second category includes seven deep learning-based methods.

- **Transformer** [19] is an encoder-decoder framework based on Self-attention mechanism.
- **CODE-NN** [20] is the first deep learning model that utilizes LSTM and attention mechanism for comment generation tasks.
- **CodeBERT** [11] is built using a transformer-based neural architecture and trained with a hybrid objective function.
- **UniXcoder** [21] is a unified cross-modal pre-trained model for programming languages, which uses a masked attention matrix to control the behavior of the model and enhances the code representation with cross-modal content such as AST and code comments.
- **CoTexT** [22] is a pre-trained transformer-based encoder-decoder model that uses self-supervision to learn representative contexts between natural language (NL) and programming language (PL).
- **PLBART** [23] is a sequence-to-sequence model that learns program syntax, style, and logical flow crucial to program semantics.
- **CodeT5** [24] is a unified pre-trained encoder-decoder model that supports multi-task learning and can better use the information of code tokens.

The third category includes three hybrid methods of considering multiple inputs.

- **Hybrid-Deepcom** [25] considers the semantic and structural information of Java code and obtains the syntactic information of the code by traversing AST.
- **Rencos** [18] first retrieves similar code and then fuses the vectors by the decoder.
- **BASHEXPLAINER** [9] is the only model in Bash comment generation. It utilizes two-stage training strategies: the fine-tuning stage and the information retrieval enhancement stage.

Bash Comment Generation via Data Augmentation and Semantic-Aware CodeBERT

Table 2 Comparison results between Bash2Com and baselines in terms of BLEU-1/2/3/4, METEOR and ROUGE-L measures

Method Type	Method Name	BLEU-1 (%)	BLEU-2 (%)	BLEU-3 (%)	BLEU-4 (%)	METEOR (%)	ROUGE-L (%)

4.4 Experimental Settings

Our proposed method and baselines are implemented using the PyTorch framework. The code for BASHEXPLANER is implemented by the code provided by Yu et al. [9]. Specifically, we utilize the Transformers ⁴ and CodeBERT ⁵ to implement our proposed method. The model is trained using the AdamW optimizer for 50 epochs, with a learning rate of 2e-4. The weight α is 0.3, and the number of times K is set to 3 in NP-GD. To reduce the time cost of the model, we have implemented the technique of early stopping with a step size of 5 in this experiment. Table 3 illustrated the specific hyper-parameter setting of Bash2Com.

Table 3 Hyper-parameters setting of Bash2Com

Category	Hyper-parameter	Value
NP-GD	K	3
	α	0.3
CodeBERT	decoder_layers	6
	hidden_size	768
	max_input_length	48
	max_output_length	64
	beam_search_size	10

We run all the experiments on a computer with an Intel(R) Xeon(R) Silver 4210 CPU and a GeForce RTX3090 GPU with 24 GB memory. The running OS platform is Windows OS.

5 Experimental Results

5.1 RQ1: How successful is our proposed method, Bash2Com, in generating Bash comments?

RQ1 aims to compare the Bash2Com with fourteen state-of-the-art baselines, illustrated in Section 4.3. These baselines can be classified into three types: information retrieval methods, deep learning methods, and hybrid methods. Table 2 shows the overall results of the different methods concerning three evaluation measures (BLEU, ROUGE-L, and METEOR), and we mark the best one of each metric in bold. As seen in Table 2, our proposed method Bash2Com outperforms all considered baselines.

Firstly, we compare Bash2Com with information retrieval baselines. The state-of-the-art method is NNGen, which utilizes cosine similarity and BLEU values to retrieve similar code, so the NNGen method has better BLEU values. However, our method Bash2Com can perform better than NNGen. Specifically, Bash2Com can improve performance by at least 8.14%, 13.01%, 15.82%, and 16.95% for BLEU-1/2/3/4 measures. Our method can also improve performance by 9.28%, and 12.90% for METEOR and ROUGE-L measures.

Secondly, we compare Bash2Com with deep learning baselines. The results show that the CodeT5 method performs best among the deep learning methods. However, for the BLEU-1/2/3/4, METEOR and ROUGE-L measures, Bash2Com can improve the performance by at least 5.78%, 9.37%, 11.85%, 13.48%, 2.61% and 7.11%. One possible reason is insufficient training data, which is challenging for deep learning models that require large amounts of training data. In contrast, Bash2Com using adversarial training is more suitable for handling small corpus, which can help to improve the model performance.

Thirdly, we compare Bash2Com with the hybrid baselines. We consider BASHEXPLAINER the baseline because it is the best-performing method among the hybrid methods and the state-of-the-art baseline for Bash code comment generation. Compared to BASHEXPLAINER, Bash2Com improves the performance by at least 5.80%, 8.36%, 10.19%, 11.81%, 5.14% and 6.13% in terms of BLEU-1/2/3/4, METEOR and ROUGE-L measures.

Then, to further analyze whether there is a significant difference between the comparison results of Bash2Com and baselines, we consider the Wilcoxon signed-rank test [63]. Since BLEU-4 is the most meaningful in the evaluation measures of BLEU, we only perform a significance test for BLEU-4. In addition, we only consider the best-performing baseline BASHEXPLAINER. The p -values are 0.0315, 0.0028 , 0.0164 for BLEU-4, METEOR, and ROUGE-L in detail, and all p -values are less than 0.05. These statistical results can reject the null hypothesis, which means significant differences exist between our method and baselines in all the measures considered.

Finally, we perform a case study by analyzing Bash code comments generated by Bash2Com and representative baselines in each category of baselines. The results are shown in Table 4. Although NNGen scored high in the

*Bash Comment Generation via Data Augmentation and Semantic-Aware CodeBERT***Table 4** Comments generated by different methods for three Bash code

ID	Example
1	<p>Bash Code: cat \$(whoami) Ground Truth: print current user's mail file NNGen: print current user name CodeT5: print file name of current user BASHEXPLAINER: print user name of current user Bash2Com: print file content of current user</p>
2	<p>Bash Code: sleep \$(expr 'date -d 03/21/2014 12:30 +%s' - 'date +%s') Ground Truth: sleep until a specific date NNGen: print day between _regex and _regex CodeT5: sleep date _timespan ago BASHEXPLAINER: print _regex day in _timespan Bash2Com: sleep until _datetime</p>
3	<p>Bash Code: echo \$(/usr/sbin/arp \$(hostname) awk -F[:] { print \$ 2 }) Ground Truth: print ip address of current host NNGen: print current host name CodeT5: print ip address of host name BASHEXPLAINER: print _regex follow by current hostname Bash2Com: print ip address of current host</p>

automatic evaluation in these cases, the generated code comments differed significantly from the ground truth. One possible reason for this is the Bash code syntax flexibility. As the best-performing baseline BASHEXPLAINER, the comments generated in the second and third examples were poorly readable and understandable. A possible reason for this is that it considers information from the retrieved corpus, and this interference affects the model's performance. In addition, the comments generated by CodeT5 are somewhat distant from the ground truth.

Summary for RQ1: Bash2Com can generate higher-quality Bash code comments than state-of-the-art baselines in an automatic evaluation way.

5.2 RQ2: How much does our proposed component, NP-GD, contribute to the effectiveness of our proposed method, Bash2Com, in achieving its objectives?

RQ2 aims to investigate the impact of three different adversarial training methods on the Bash code comment generation task. In particular, we consider the popular adversarial training methods (i.e., FGSM [26], FGM [27] and PGD [28]). FGSM aims to make the disturbance direction δ by following the gradient direction and takes the max normalization of the gradient by the *sign* function. Unlike FGSM, which takes the same steps in each direction, FGM scales according to specific gradients to obtain better adversarial examples. FGM uses L_2 normalization, which divides the value of each gradient dimension by the L_2 parameter of the gradient.

Table 5 shows the comparison results of using different adversarial training methods. The experimental results show that utilizing NP-GD can significantly improve the model performance. Specifically, compared to Bash2Com without NP-GD, Bash2Com can improve the performance by 13.28%, 15.17%, 8.26%

Table 5 Ablation study results for adversarial training methods in Bash2Com

Setting	BLEU-3	BLEU-4	METEOR	ROUGE-L
w/o NP-GD	32.83	28.28	27.95	49.18
with FGSM	28.70	25.22	26.12	47.99
with FGM	33.74	29.14	27.82	49.20
with PGD	34.42	29.91	28.65	49.57
Bash2Com	37.19	32.57	30.26	51.80

and 5.33% for BLEU-3, BLEU-4, METEOR, and ROUGE-L respectively. This result indicates that our data augmentation component NP-GD is significantly valuable for the Bash code comment generation task. At the same time, the experimental results also show that NP-GD can achieve the best performance among the different adversarial training methods. NP-GD can improve the performance by 8.05%, 8.89%, 5.62%, and 4.50% for BLEU-3, BLEU-4, METEOR, and ROUGE-L respectively, compared to the best-performing baseline method PGD. This result shows that our proposed NP-GD can fully use the advantages of L_1 normalization and L_2 normalization, which eventually improves the stability of the normalization process and makes it more suitable for the Bash code comment generation task.

Summary for RQ2: For the Bash code comment generation task, NP-GD can contribute more than traditional adversarial training methods.

5.3 RQ3: How much does our proposed component, MASA, contribute to the effectiveness of our proposed method, Bash2Com, in achieving its objectives?

RQ3 aims to conduct an ablation study to demonstrate the effectiveness of semantic-aware component MASA utilized by our proposed method Bash2Com. Specifically, we set up four control methods:

- (1) without MASA: To verify the necessity of a semantic-aware component, we directly utilize the output of the last layer of CodeBERT as the learned feature information into the decoder to generate Bash code comments;
- (2) with GRU: To verify the ability of different RNN models to aggregate feature information in this method, we utilize GRU-Attention [29] to fuse the feature information output from each layer of CodeBERT into the decoder to generate Bash code comments;
- (3) with Bi-LSTM: To verify the ability of different RNN models to aggregate feature information in this method, we utilize Bi-LSTM-Attention [30] to fuse the feature information output from each layer of CodeBERT into the decoder to generate Bash code comments;

*Bash Comment Generation via Data Augmentation and Semantic-Aware CodeBERT***Table 6** Ablation study results for Semantic-aware methods of Bash2Com

Setting	BLEU-3	BLEU-4	METEOR	ROUGE-L
w/o MASA	33.55	28.98	28.31	48.86
with GRU	34.44	29.83	28.75	49.34
with Bi-LSTM	34.83	30.24	28.82	49.81
Bash2Com	37.19	32.57	30.26	51.80

(4) with MASA: This is the component applied by Bash2Com, which utilizes LSTM + Attention to fuse the feature information output from each layer of CodeBERT into the decoder to generate Bash code comments.

Table 6 shows the results of the ablation experiments. After comparing these control methods, Bash2Com with MASA can achieve the best performance. Specifically, compared to no MASA, Bash2Com with MASA can improve the performance by 10.85%, 12.39%, 6.89% and 6.02% for BLEU-3, BLEU-4, METEOR, and ROUGE-L respectively. This result shows that LSTM can effectively fuse representative information from CodeBERT output, which helps to improve the quality of the generated Bash code comments. In addition, compared with other variants of RNNs, Bash2Com with MASA can improve the performance by at least 6.78%, 7.71%, 5.00%, and 4.00% for BLEU-3, BLEU-4, METEOR, and ROUGE-L respectively. This result indicates that MASA can fuse the representative information from CodeBERT output more effectively than other variants of RNNs in this ablation experiment, which can ultimately improve the quality of the generated Bash code comments.

Summary for RQ3: The utilization of MASA by Bash2Com is shown to enhance model performance, with the LSTM model selected by MASA demonstrating superior performance compared to other RNN variants.

6 Discussion

6.1 Analysis on the Hyper-parameters setting

In this subsection, we perform a sensitivity analysis on the parameters of Bash2Com. We mainly focus on two parameters (i.e., the number of decoder layers *decoder_layers* and the number of adversarial examples *K*). The results of the sensitivity analysis are shown in Fig. 4 and Fig. 5, where all hyperparameters except the hyperparameter of the current analysis are set to the optimal setting. Since the numerical differences in evaluation measures, the left axis is used for BLEU and METEOR, and the right axis is used for ROUGE-L. The optimal settings are set as follows: *decoder_layers* is 6, and *K* is 3.

In Fig. 4, we find that the best performance is achieved for all four evaluation metrics when the number of layers of the decoder is 6. When the number of layers of the decoder is increased from 2 to 6, the scores of the four evaluation measures show a decreasing trend followed by an increasing trend. When

the number of layers of the decoder is larger than 6, the scores of the four evaluation measures show a flat decreasing trend. When the number of generated adversarial examples changes from 1 to 5, the four evaluation measures shown in Fig. 5 show an overall trend of rising first and then declining, and we set the value of this parameter to 3 since it can achieve the best performance. In our experiments, to balance the performance and cost of the model, we set the number of decoder layers to 6 and the number of generated adversarial examples to 3.

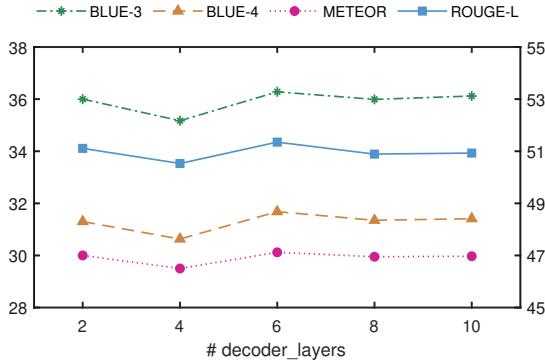

Fig. 4 Sensitivity Analysis on the number of decoder layers (the left axis is used for BLEU and METEOR, and the right axis is used for ROUGE-L)

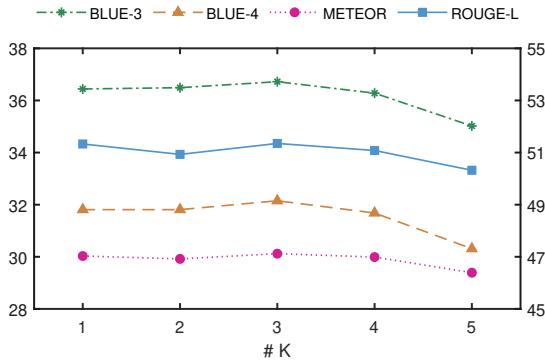

Fig. 5 Sensitivity Analysis on the number of adversarial examples (the left axis is used for BLEU and METEOR, and the right axis is used for ROUGE-L)

6.2 Human Study

Although automatic evaluation measures can calculate the textual dissimilarity between automatically generated comments and human-written comments, they cannot accurately distinguish the semantic similarity between them

Bash Comment Generation via Data Augmentation and Semantic-Aware CodeBERT

[18, 56, 64, 65]. Therefore, we introduced the following three metrics for our human study:

- Informativeness: Informativeness focuses only on the amount of information in the automatically generated comments without fluency.
- Similarity: Similarity is the degree of similarity between automatically generated and human comments.
- Naturalness: Naturalness considers the grammatical and fluency of automatically generated and human comments.

The score ranges from 0 to 4; the higher the score, the better the comment can meet the requirements. The final score is averaged.

For the human study, we selected NNGen, CodeT5, BASHEXPLAINER, and our proposed method Bash2Com as they are state-of-the-art methods with the best performance in their respective categories. We recruited ten volunteers: two PhDs and eight Masters - who have extensive experience in Linux development and maintenance to evaluate the automatically generated comments. We randomly selected 100 code pairs from the corpus, including Bash code and comments, and provided manual comments for reference. The volunteers rated the comments generated by the four methods based on similarity, naturalness, and informativeness. To ensure fairness, we ensured that each volunteer did not know how the comments they received were generated. Additionally, to ensure the quality of the labels, we limited the number of Bash codes each volunteer marked to 25 per day.

Table 7 presents the human study results between Bash2Com and three representative baselines. The results show that our method Bash2Com significantly improved over three baselines on Informativeness and Similarity but is slightly lower than NNGen by 0.06 points on the Naturalness metric. One possible reason is that NNGen is based on an information retrieval method, and the generated Bash code comments are obtained from the original corpus. Since professional developers write these comments, they are more natural. On the other hand, the comments generated by Bash2Com are only 0.06 points below in the Naturalness metric, which indicates that Bash2Com is also effective in naturalness.

Table 7 Comparison results of our human study (standard deviation in parentheses)

Method	Informativeness	Naturalness	Similarity
NNGen	1.81(1.22)	3.63 (0.99)	1.49(1.03)
CodeBERT	2.18(1.14)	3.21(1.10)	1.71(1.29)
BASHEXPLAINER	2.76(1.34)	3.51(0.89)	2.38(1.45)
Bash2Com	2.83 (1.09)	3.57(0.75)	2.51 (1.17)

To assess the differences in volunteer scoring results, we consider Fleiss Kappa [66] to measure the evaluation consistency of these volunteers. The result was 0.748, representing the consistency of the scoring results of the volunteers.

6.3 Impact Analysis of Code Lengths and Comment Lengths

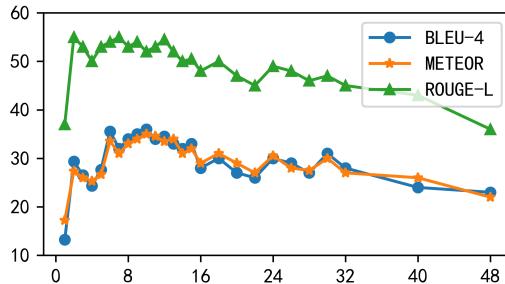

Fig. 6 Analysis on the impact of different code lengths

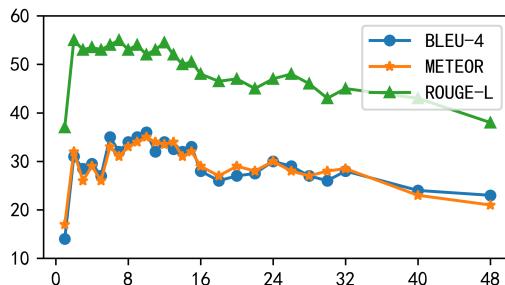

Fig. 7 Analysis on the impact of different comments lengths

In this subsection, we analyze the performance of Bash2Com in different code lengths and comment lengths with BLEU-4, METEOR, and ROUGE-L. The results of the influence results can be found in Fig. 6 and Fig. 7. Based on the experimental results, we find that the performance of Bash2Com is consistent with the statistical distribution of the corpus.

According to the corpus statistics in Table 1, we know that the length of most Bash code and the corresponding comments are mainly around 8 or 11 words in the corpus. In addition, 90.8% (80.3%) of Bash code (comments) is less than 16 words in length. Based on these training sets, Bash2Com is stable in length from 1 to 16. Moreover, because there are data with a length of more than 32, the performance of the model declines. This result indicates that our data augmentation technology is valuable for the Bash code comment generation task. Therefore, collecting more corpus according to our length analysis in the future can further strengthen our Bash code comment generation method Bash2Com.

6.4 Performance Analysis of ChatGPT

Large language models (LLMs) have been used for many mainstream software engineering tasks, which refer to a class of artificial intelligence models that

*Bash Comment Generation via Data Augmentation and Semantic-Aware CodeBERT***Table 8** Comparison results of ChatGPT and Bash2Com

Method	BLEU	METEOR	ROUGE-L	CIDEr
ChatGPT	10.92	6.91	10.91	10.02
ChatGPT(PL)	18.51	10.64	17.49	17.75
Bash2Com	42.07	30.26	51.80	26.14

use an enormous amount of parameters and are designed to process and generate human-like text based on large-scale language datasets [67]. In our study, we also designed related experiments to verify the performance of LLMs in Bash code comments generation task. The model used in our experiment is GPT3.5, a widely used version of ChatGPT⁶. The first row of results is generated directly using ChatGPT. The second result is prompt learning (PL) technology [68], which can be used as an expert question and answer to better play LLM’s ability in related fields. The BLEU is the average value of BLEU-1/2/3/4, and we added CIDEr [69] to evaluate the model performance further.

Table 8 shows the comparison results of Bash2Com and ChatGPT. The results show that our method Bash2Com improved over ChatGPT. Specifically, in the automatic index evaluation, ChatGPT(PL) performs better than the native ChatGPT, but both are behind Bash2Com. This result indicates that ChatGPT needs advanced professional knowledge to play its performance, but Bash code, as a small language, does not have too many corpora to train the GPT model. ChatGPT can be optimized through prompt learning technology, but it may need more data support, and we will also pay attention to it in future research.

6.5 Limitations of Bash2Com

Our automatic evaluation showed that our proposed method Bash2Com outperformed the baselines. However, we also noticed that Bash2Com may generate comments of lower quality than the ground truth. In this subsection, we identify three challenges and analyze each. More details can be found on our homepage ⁷.

The first challenge is that when technicians write comments, synonyms are diversified. For example, “search system for file _file” and “find all files under _file and sort them” contain some synonyms, but the mixed words cause Bash2Com prediction error. One possible solution is to standardize comment writing and avoid mixing synonymous words.

The second challenge arises when some common fields of Bash code are overwritten. For example, some Bash code snippets find or remove files under a certain path. The original Bash code is “find ask : ask/www/askapache” or “rm ask : ask/www/askapache”, but it became “find Path” or “rm File” after preprocessing. This operation is helpful for Bash2Com to learn more

⁶<https://chat.openai.com/>

⁷https://github.com/syhstudy/Bash2Com/blob/master/limitation_data.csv

important semantic information in Bash code. However, it will also make some code inputs too short, making Bash2Com difficult to learn semantics.

The third challenge is that the current model’s performance can still be improved. Therefore, further augmenting the training data and improving the diversity of the contained Bash code and comments may alleviate this issue.

6.6 Threats to Validity

Internal threats. The first internal threat is the potential faults in implementing Bash2Com. To mitigate this threat, we utilize mature libraries(such as PyTorch and transformers) to implement the methods. The second internal threat is the randomness of adversarial training to generate adversarial examples. To mitigate this threat, we guarantee the replicability of our method by fixing random seeds. The third internal threat is the baselines considered in RQ1. For these baselines, we use the scripts shared by Yu et al.⁸. Then, we reproduce other baseline models according to original studies and achieve similar performance.

External threats. The main external threat to this study is the corpus. To mitigate this problem, we performed data augmentation using adversarial training. Also, we follow the previous study’s settings [9] in the division of the corpus to ensure a fair comparison.

Construct threats. Construct threats mainly refer to the selection of automatic assessment measures. To mitigate these threats, we chose three performance measures: BLEU [52], METEOR [53], and ROUGE-L [54]. These evaluation measures are widely utilized in the field of neural machine translation and automatic comment generation [18, 55–62]. We also conduct a human study and compute the p-value by using the Wilcoxon signed-rank test to evaluate the readability, comprehensibility, and naturalness of Bash comments generated by our proposed method and representative baselines.

Conclusion threats. We only split the corpus once because of the high computational cost of deep learning. This setting is consistent with the previous study on Bash code comment generation [9]. To mitigate the conclusion threat, we also randomly split the corpus three times by different random seeds, and we show detailed comparison results on the project homepage⁹, which also confirms the effectiveness of our proposed method when compared with baselines.

7 Related Work

7.1 Code Comment Generation

Code comment generation [70–72] is a task that generates comments for a piece of the source code. We classify these methods into the following

⁸<https://github.com/NTDXYG/BASHEXPLAINER>

⁹https://github.com/syhstudy/Bash2Com/blob/master/README_add.md

Bash Comment Generation via Data Augmentation and Semantic-Aware CodeBERT

three categories: Information retrieval-based, Deep learning-based, and hybrid methods.

Information retrieval-based methods were first investigated, often achieving better high-reusable code performance. Haiduc et al. [17] first proposed VSM (Vector Space Model) and LSI (Latent Semantic Index) to retrieve relevant terms from a corpus to generate comments on classes and methods. Then Eddy et al. [73] extended it to a thematic model hPAM to build code comments. Recently, Yang et al. [8] proposed the method CCGIR based on semantic similarity, lexical similarity, and syntactic similarity of smart contract code.

Regarding deep learning-based methods, Iyer et al. [74] first proposed CODE-NN, a deep learning method using LSTM and attention mechanism to build the encoder and decoder. Hu et al. [6] proposed the DeepCom method, which considers Java code's semantic and structural information. Later, they proposed the SBT method to convert abstract syntax trees into AST sequences. Recently, Yang et al. [7] proposed a Transformer-based method, ComFormer, which uses semantic and syntactic information of the code to learn code semantics.

Some recent studies have proposed a hybrid method that combines multiple inputs. Wei et al. [56] proposed the Re²Com method, which retrieves similar code snippets and then reuses existing comments as examples to guide comment generation. Zhang et al. [18] proposed the Rencos method, which considers syntactic and semantic similarity. Rencos retrieves the two most similar code fragments from the corpus, generates fusion vectors, and then decodes the fusion vectors to generate comments.

However, most of the existing comment-generation methods focus on popular programming languages. In this study, we focus on a specific programming language Bash, and propose a novel Bash comment generation method Bash2Com. Aiming at the challenges faced by Bash code comment generation, such as insufficient corpus, we propose a data enhancement component named NP-GD. Moreover, we further propose a semantic awareness component, MASA, to learn the semantic representation of Bash code better. Both automatic evaluation and human study verify the effectiveness of our study.

7.2 Data Augmentation in NLP

In natural language processing, typical data augmentation methods can be categorized as rule-based and gradient-based. For the former, Wei and Zou [32] proposed the EDA method, which includes some easy data augmentation operations. Xie et al. [33] proposed the UDA algorithm related to noncore word replacement technology, that is, to replace a certain proportion of nonimportant words in the text with unimportant words in the dictionary to generate new text. Anaby et al. [75] proposed a GPT-based data augmentation technology, LAMBDA, which first pre-trained and then fine-tunes the model on a small number of corpus for different tasks.

For the gradient-based data augmentation technology (e.g., adversarial training), Miyato et al. [27] introduced adversarial training and virtual adversarial training [76] into the NLP domain to improve the performance of classification models. Ebrahimi et al. [77] proposed using character/word substitution (white-box method) to generate adversarial examples. Zhu et al. [37] utilized a gradient-based method to add adversarial perturbations to the embedding of input sentences, allowing the model to improve performance in the field of natural language understanding. Recently, Zhang et al. [78] also found that model performance can significantly improve in code comment generation by generating adversarial examples.

To the best of our knowledge, no research has focused on the performance of adversarial training in bash code comment generation. We consider adversarial training in our method Bash2Com to fill this gap. Moreover, to better adapt to our task, we designed a customized adversarial training method NP-GD, which uses L_1 normalization to reduce the effect of large values on the vectors and then applies L_2 normalization to ensure that the resulting vectors have a consistent length and sum to 1.

7.3 Bash Code Comment Generation

Lin et al. [2] were the first to study the field of Bash code and constructed a corpus of Bash code using natural language descriptions. Yu et al. [9] further enriched the corpus based on the study of Lin et al. [10]. They combined the NL2Bash study with the corpus shared in the NLC2CMD competition to construct a corpus with 10,592 Bash code and corresponding comments. They also propose an automatic generation model BASHEXPLAINER for Bash code comments based on a two-stage training strategy.

However, Yu et al. [9] only used information retrieval methods to enhance input representation. Motivated by the Bash code comment generation task, we introduce the idea of data augmentation and multi-layer semantic awareness, making the model fine-tuned on a larger corpus and learning the multi-level semantic representation.

8 Conclusion

In this study, we propose a novel Bash comment generation method Bash2Com, which includes two components NP-GD and MASA. Specifically, NP-GD is designed to enhance the data representation. In NP-GD, the data is augmented by acting on the adversarial training of the embedding layer. MASA is designed to represent better information learned by each layer in CodeBERT. In MASA, the representation information of each layer of CodeBERT is fully utilized using LSTM, and weights are assigned to each layer using an attention mechanism. Finally, the Transformer decoder utilizes the output vector to generate the corresponding Bash comment. We evaluate the effectiveness of the Bash2Com through extensive experiments, which show that our proposed method outperforms state-of-the-art baselines.

In the future, we want to evaluate the effectiveness of our proposed method by extending it to more low-resource source code understanding tasks. Moreover, we also want to further improve our proposed method's performance by considering more advanced code representation and adversarial training methods.
